EXPERIMENT 15

CREATE AND TEST A VIRTUAL MACHINE SNAPSHOT

Aim

To create a snapshot of an Ubuntu virtual machine in VMware Workstation and restore the virtual machine to the saved state.

Software Requirements

1. VMware Workstation Pro
2. Ubuntu 18.04.3 LTS virtual machine

Procedure

1. Open VMware Workstation and select the Ubuntu 64-bit virtual machine.
2. Start the virtual machine and log in to Ubuntu.
3. Open VM > Snapshots > Take Snapshot.
4. Enter the snapshot name as Experiment15_Snapshot and provide a short description.
5. Click Take Snapshot and wait for VMware to finish creating the snapshot.
6. Open Snapshot Manager and select Experiment15_Snapshot.
7. Click Go To and confirm the restoration if VMware asks for confirmation.
8. Wait for the virtual machine to return to the saved state.

Observation

VMware Snapshot Manager displayed the snapshot named Experiment15_Snapshot. The Ubuntu virtual machine returned to its terminal session screen after the restore operation. This is consistent with the snapshot restoration workflow. A separate before-and-after file test was not performed.

Screenshots

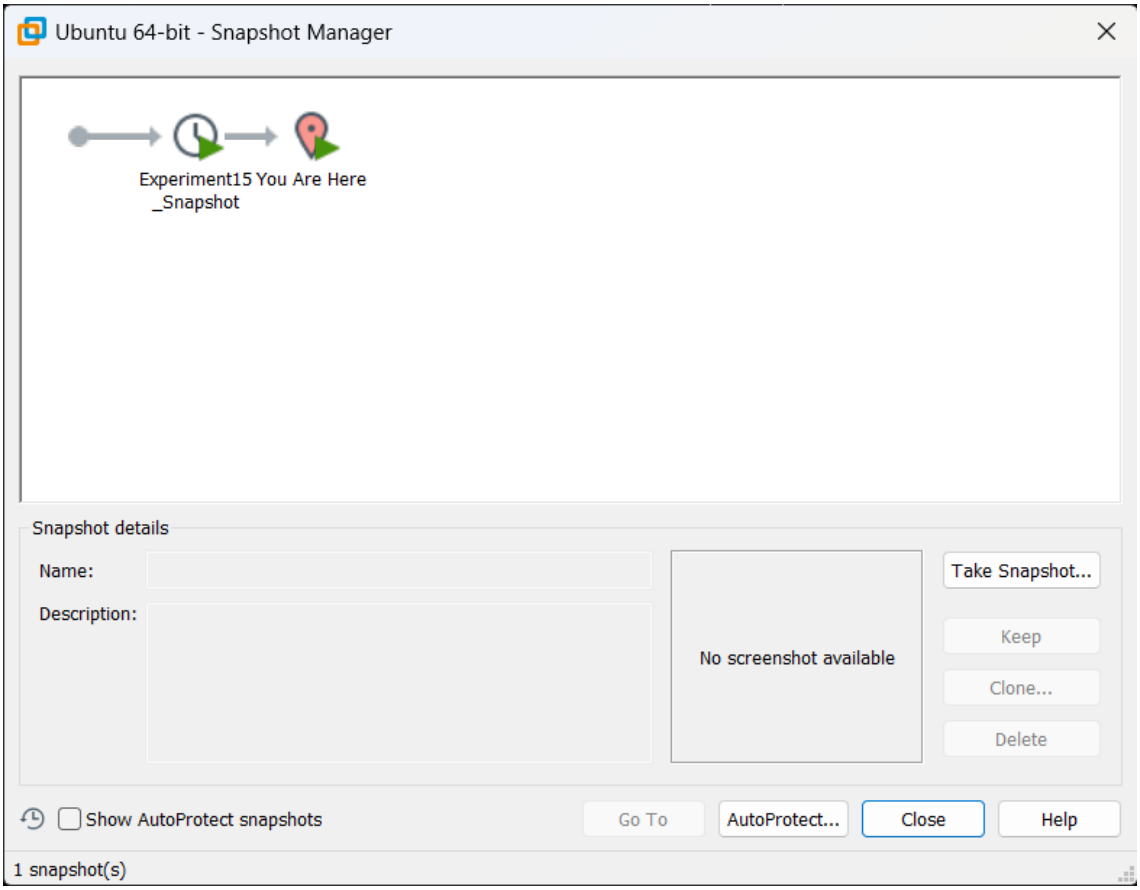

Figure 1: VMware Snapshot Manager showing Experiment15_Snapshot and the current position.

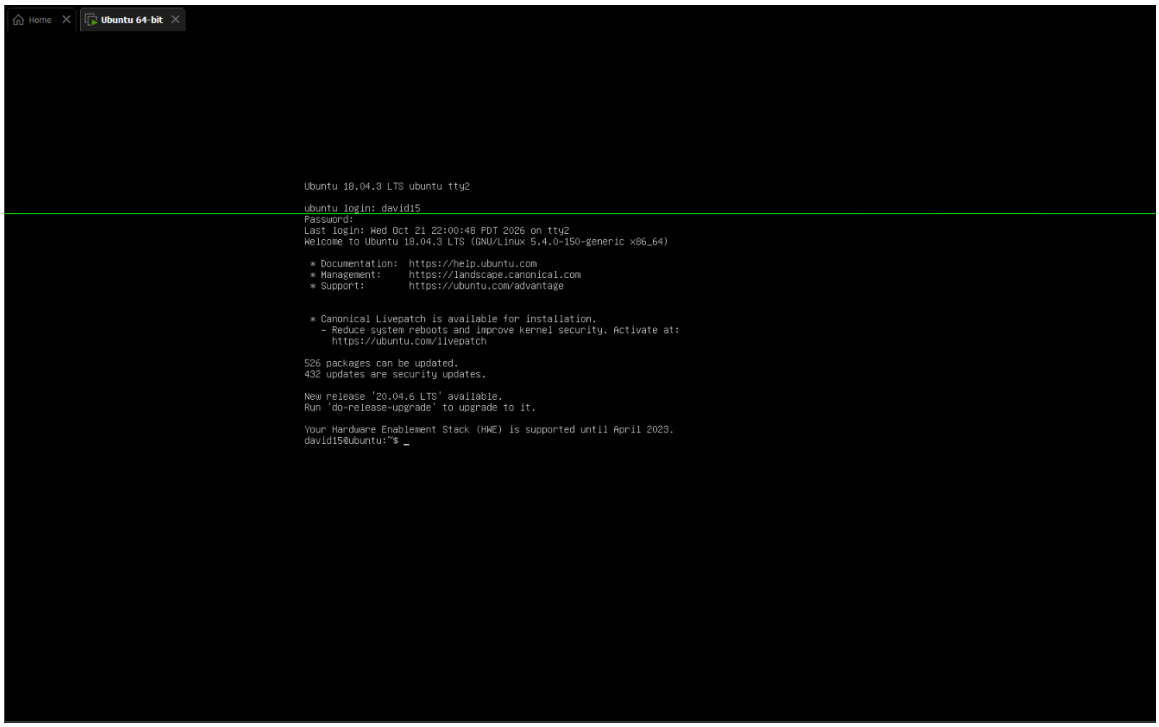

Figure 2: Ubuntu terminal screen after the snapshot restoration operation.

Result

A snapshot named Experiment15_Snapshot was created successfully in VMware Workstation, and the restore operation was carried out. The experiment demonstrated the basic use of snapshots to return a virtual machine to a previously saved state.
